

# Exploring fundamental physics with galaxy redshift surveys

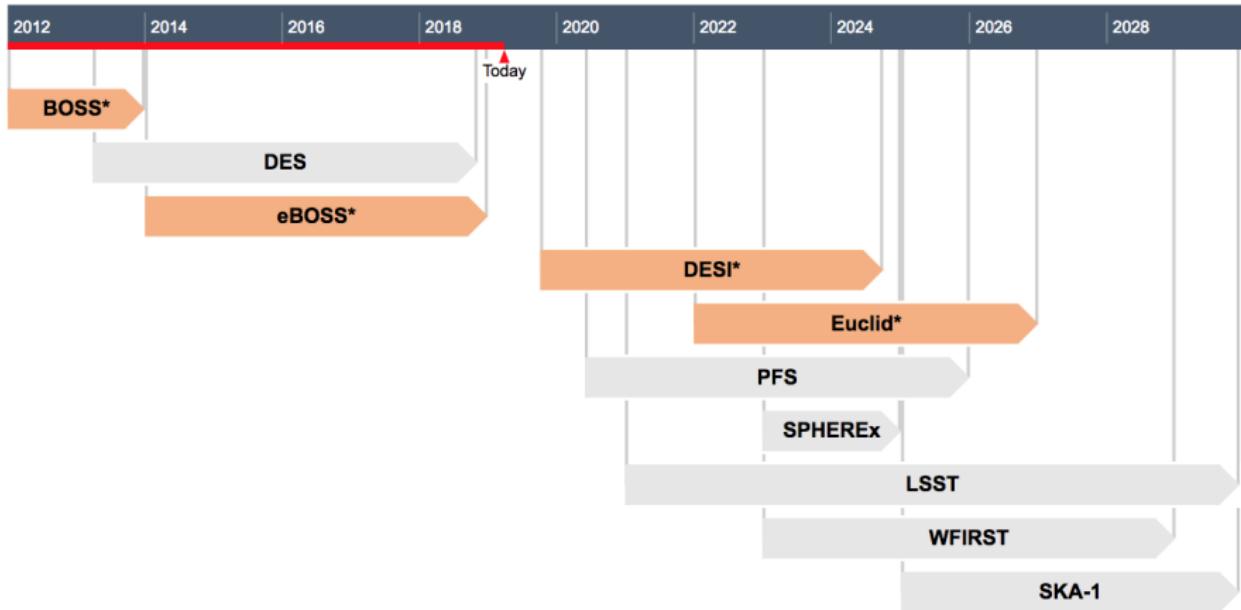

Florian Beutler

Royal Society University Research Fellow

- ① General introduction to galaxy redshift surveys
  - Baryon Acoustic Oscillations
  - Redshift-space distortions
- ② Testing inflation with primordial non-Gaussianity and primordial oscillations
- ③ Neutrinos in the phase of the BAO

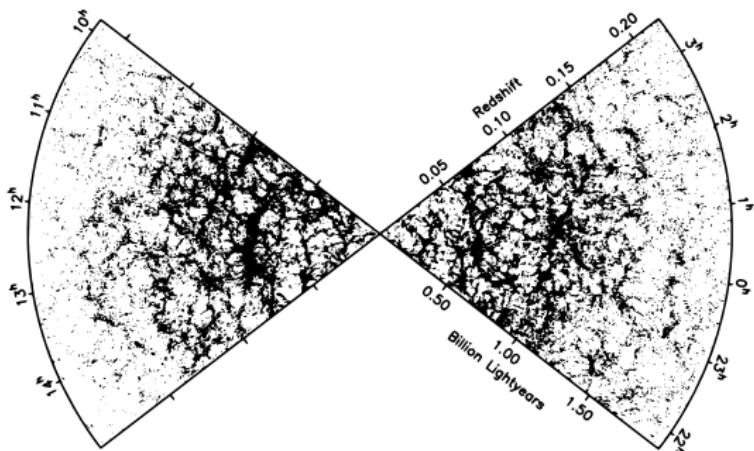

# Why should you care?

- DESI will start observing this year!

\*Collaboration Member

# What is a galaxy redshift survey?

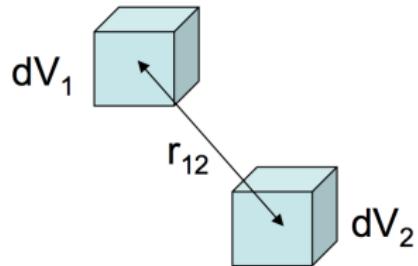

- Measure the position of galaxies (redshift + RA, DEC).
- The CMB tells us a lot about the initial conditions for today's distribution of matter.
- How the initial density fluctuations in the CMB evolved from redshift  $z \sim 1100$  to today depends on  $\Omega_m$ ,  $\Omega_\Lambda$ ,  $H_0$  etc.

# From a point distribution to a power spectrum

- Overdensity-field:

$$\delta(\mathbf{x}) = \frac{\rho(\mathbf{x}) - \bar{\rho}}{\bar{\rho}}$$

- Two-point function:

$$\xi(\mathbf{r}) = \langle \delta(\mathbf{x} + \mathbf{r}) \delta(\mathbf{x}) \rangle \begin{cases} \text{homogeneity} \\ \text{isotropy} \\ \text{anisotropy} \end{cases} = \xi(r) \\ \xi_\ell(r) = \int_{-1}^1 d\mu \xi(r, \mu) \mathcal{L}_\ell(\mu)$$

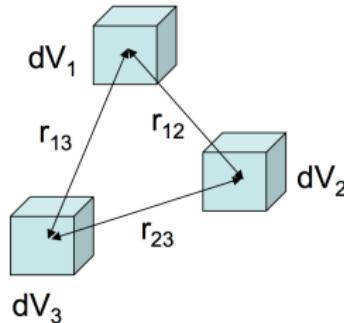

- ...and in Fourier-space:

$$P_\ell(k) = 4\pi(-i)^\ell \int r^2 dr \xi_\ell(r) j_\ell(kr)$$

# From a point distribution to a bispectrum

- Overdensity-field:

$$\delta(\mathbf{x}) = \frac{\rho(\mathbf{x}) - \bar{\rho}}{\bar{\rho}}$$

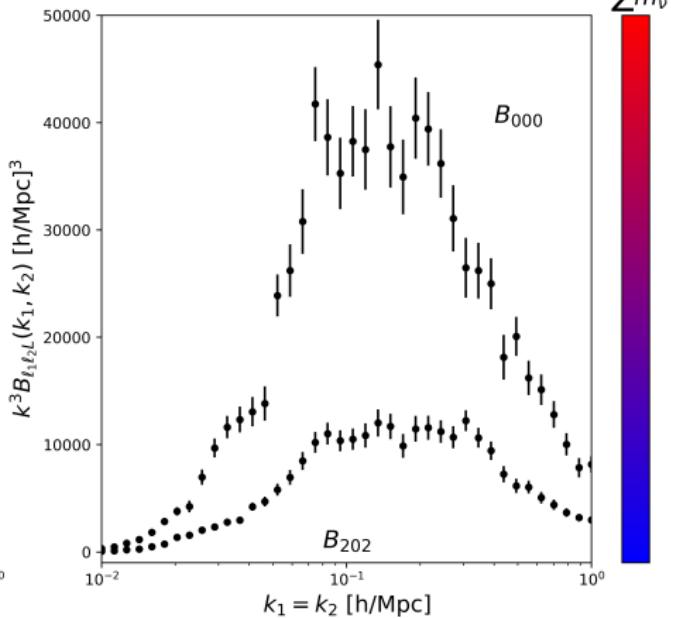

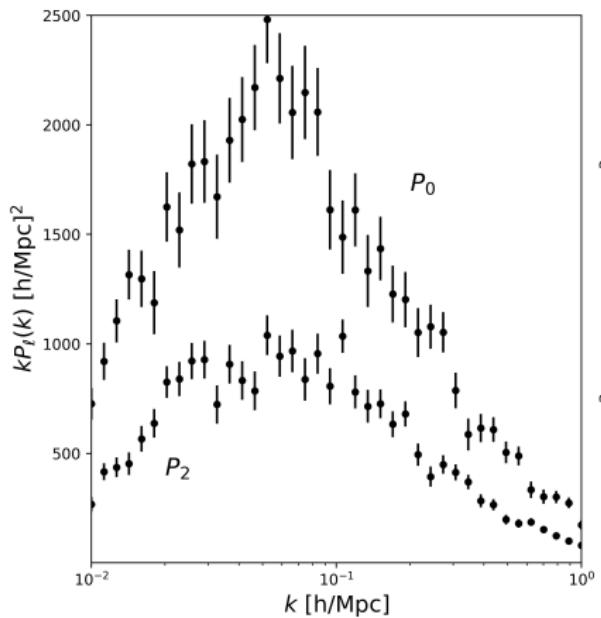

- Three-point function:

$$\xi(\mathbf{r}_1, \mathbf{r}_2) = \langle \delta(\mathbf{x} + \mathbf{r}_1) \delta(\mathbf{x} + \mathbf{r}_2) \delta(\mathbf{x}) \rangle \begin{cases} \text{homogeneity} \\ \text{isotropy} \\ \text{anisotropy} \end{cases} \rightarrow \xi_L(r_1, r_2) \\ \xi_{\ell_1 \ell_2 L}(r_1, r_2)$$

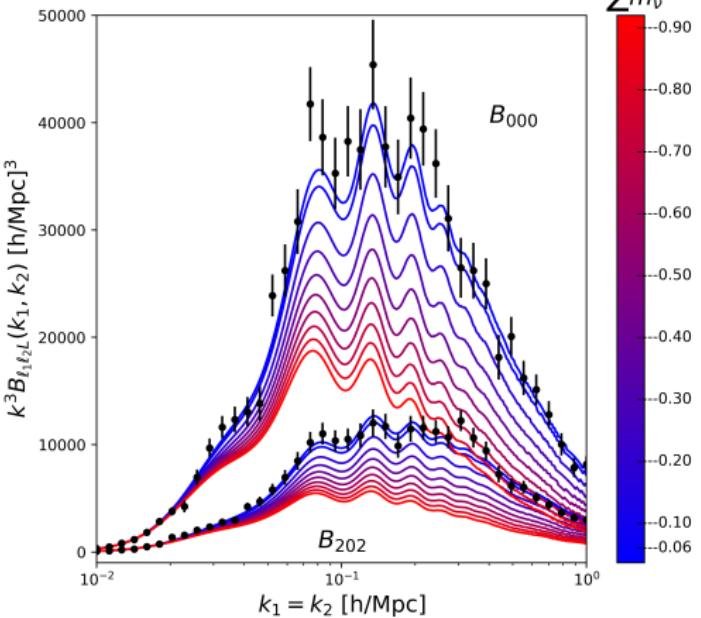

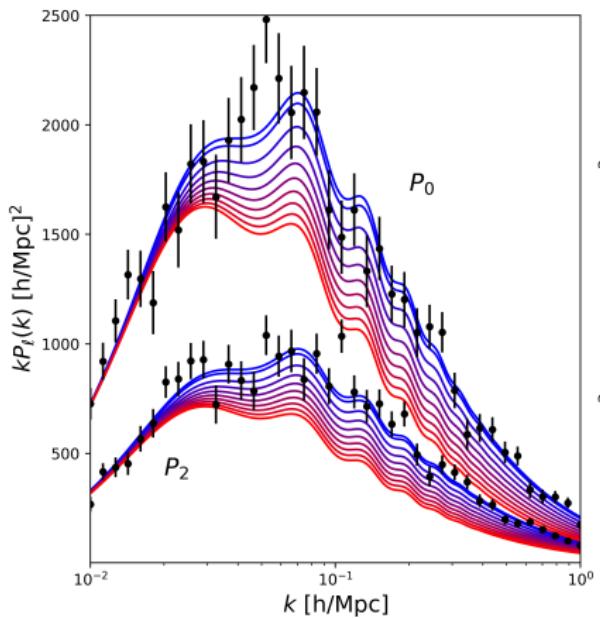

- ...and in Fourier-space:

$$B_{\ell_1 \ell_2 L}(k_1, k_2) = (4\pi)^2 (-i)^{\ell_1 + \ell_2} \int r_1^2 dr_1 \int r_2^2 dr_2 \xi_{\ell_1 \ell_2 L}(r_1, r_2) j_{\ell_1}(k_1 r_1) j_{\ell_2}(k_2 r_2)$$

# What are Baryon Acoustic Oscillations?

# What are Baryon Acoustic Oscillations?

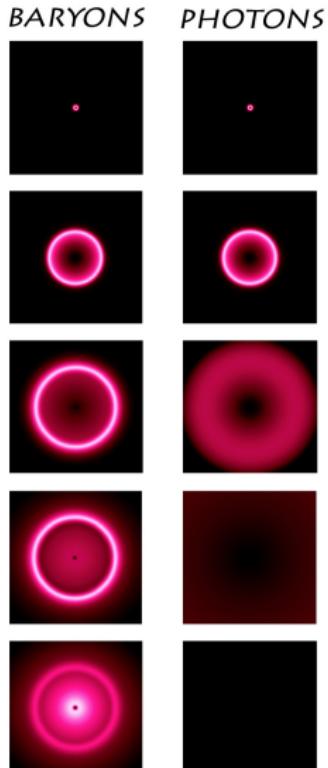

- For the first 380 000 years the evolution eq. of baryon and photon perturbations can be written as

$$\ddot{\delta}_{b\gamma} - c_s^2 \nabla^2 \delta_{b\gamma} = \nabla^2 \Phi$$

with the plane wave solution

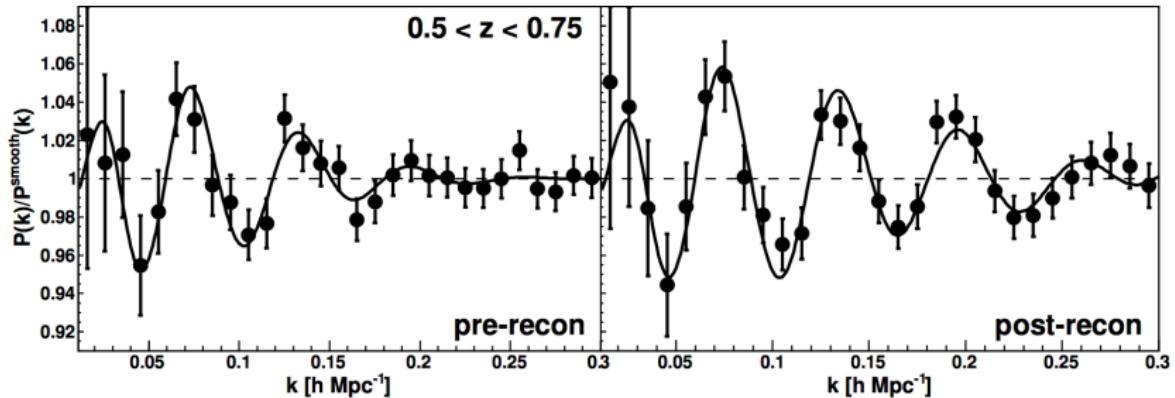

$$\delta_{b\gamma} = A \cos(kr_s + \phi)$$

- Preferred distance scale between galaxies as a relic of sound waves in the early Universe.
- This signal is present at low redshift and detectable in  $\xi(r)/P(k)$  **on very large scales**.

credit: Martin White

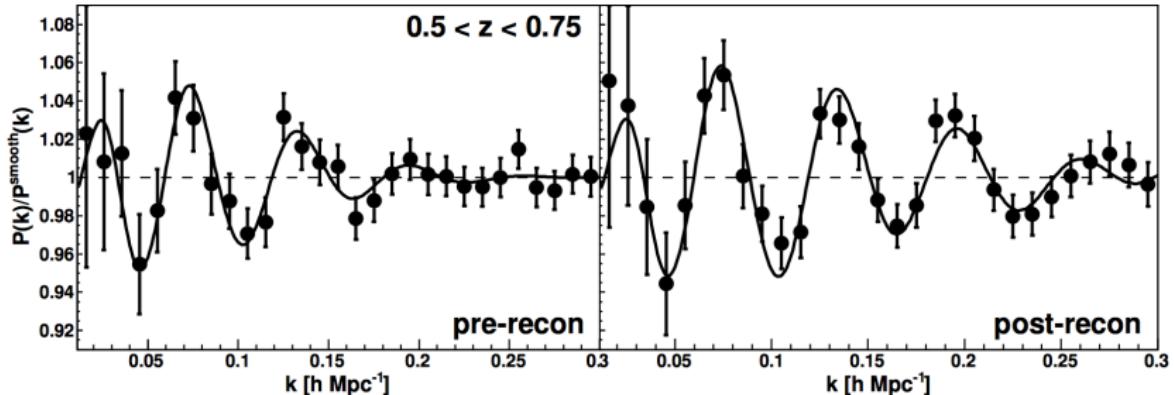

# Baryon Acoustic Oscillations in BOSS

$$D_A(z) = \int_0^z \frac{cdz'}{H(z')}$$

$$H(z) = H_0 \sqrt{\Omega_m (1+z)^3 + \Omega_\Lambda + \Omega_k (1+z)^2}$$

# Baryon Acoustic Oscillations in BOSS

$$D_V(z = 0.38) r_s^{\text{fid}}/r_s = 1476 \pm 15 \text{ Mpc} \quad (1.0\%)$$

$$D_V(z = 0.61) r_s^{\text{fid}}/r_s = 2146 \pm 19 \text{ Mpc} \quad (0.9\%)$$

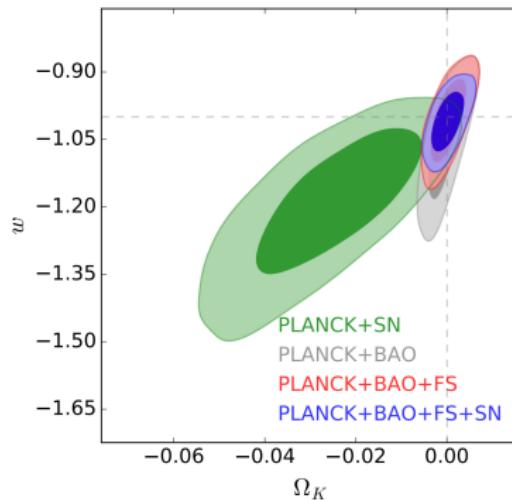

$$D_V(z) = \left[ (1+z)^2 D_A^2(z) \frac{cz}{H(z)} \right]^{1/3}$$

# Baryon Acoustic Oscillations in BOSS

- The BAO signal is located on very large scales and can be captured (mostly) with a linear model.
- In BOSS we used an agnostic broadband marginalisation using a set of polynomial terms and density field reconstruction to boost the signal.
- Due to BAO we now know the distance to  $z = 0.38$  and  $z = 0.61$  with  $\sim 1\%$  uncertainty... **better than our knowledge of  $H_0$ .**

# What are redshift-space distortions?

The densities along the line-of-sight are enhanced due to the velocity field

$$\begin{aligned}\delta_g(k) &= b_1 \delta_m(k) - \mu^2 \nabla \cdot \mathbf{v} \\ &= \delta_m(k)(b_1 + f\mu^2)\end{aligned}$$

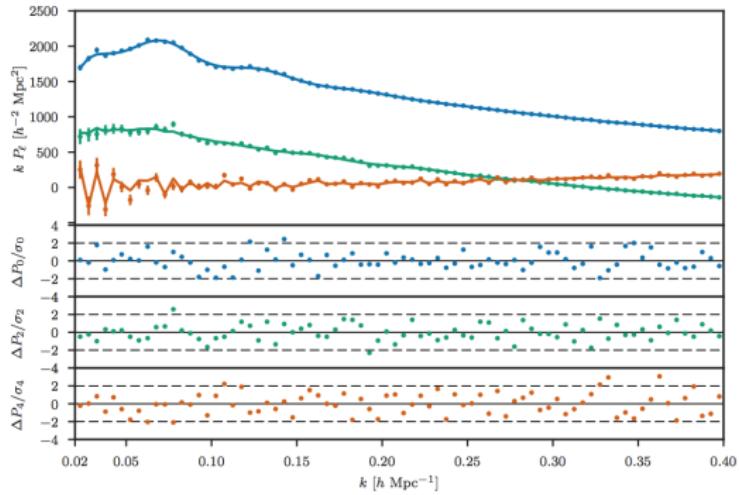

- Introduces a quadrupole
- Sensitive to cosmology since

$$f = \frac{\partial \ln D}{\partial \ln a} \approx \Omega_m^{0.55}$$

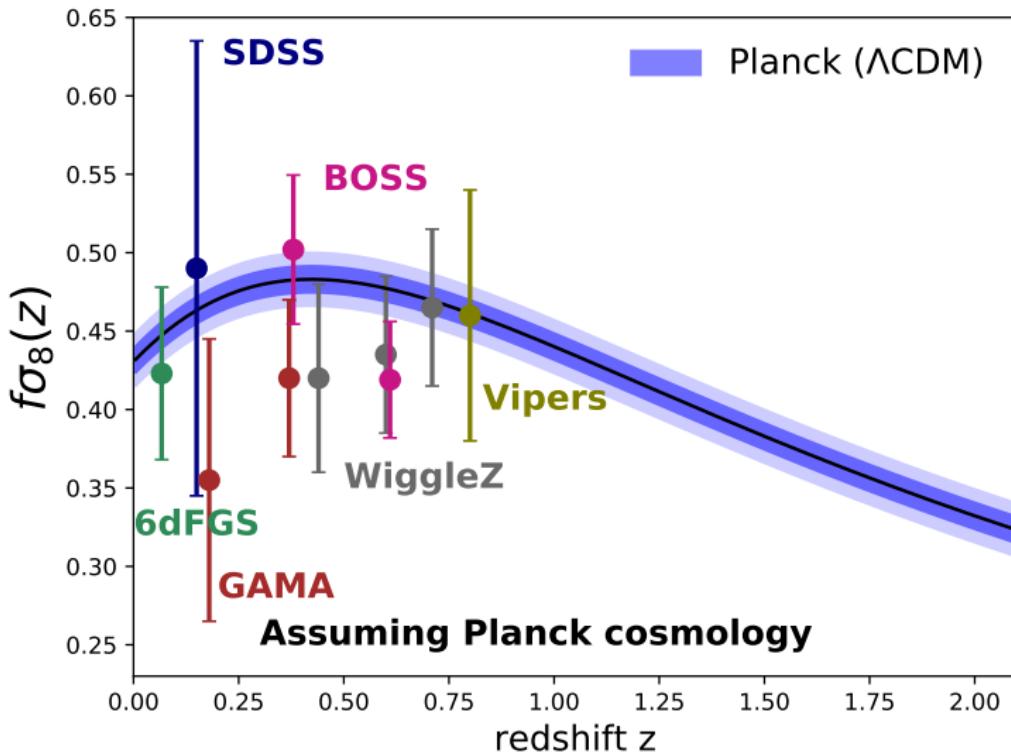

Alam + Beutler et al. (2017)

# Broadband modelling - Distribution function model

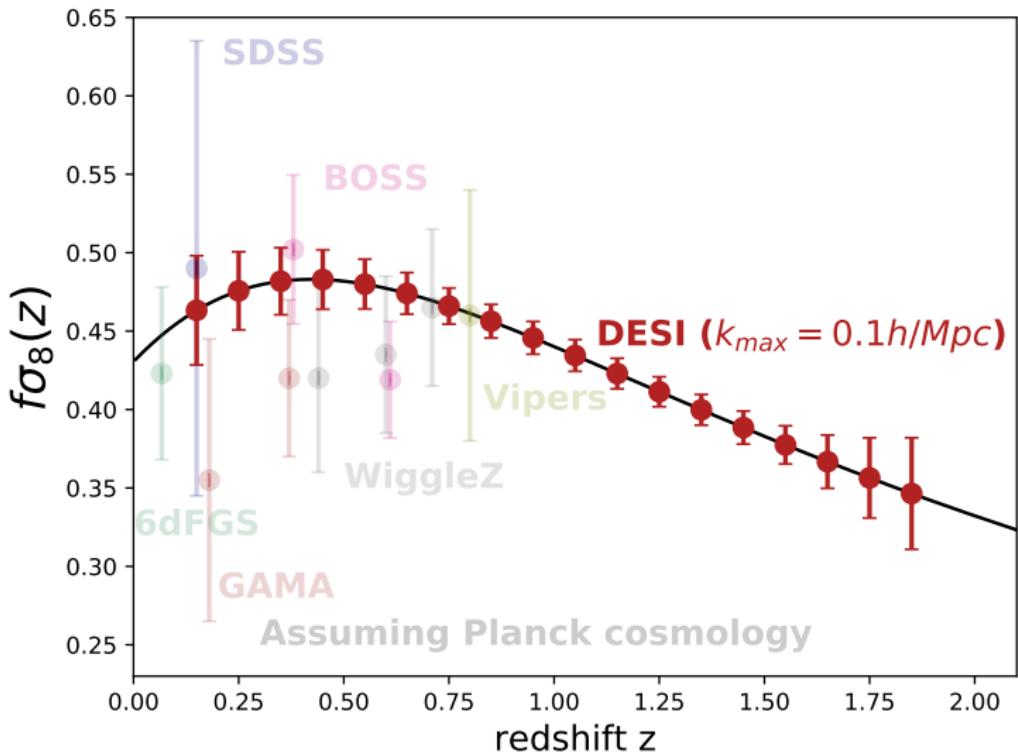

- Can model the power spectrum up to  $k_{\max} = 0.4h/\text{Mpc}$  using 9 nuisance (HOD based) parameters.
- We still have to **include the bispectrum** to constrain the nuisance parameters.

# Constraining the neutrino mass with BAO & RSD

$$|\Delta m_{31}^2| \approx 2.56 \times 10^{-3} \text{ eV}^2$$
$$\Delta m_{21}^2 \approx 7.37 \times 10^{-5} \text{ eV}^2$$

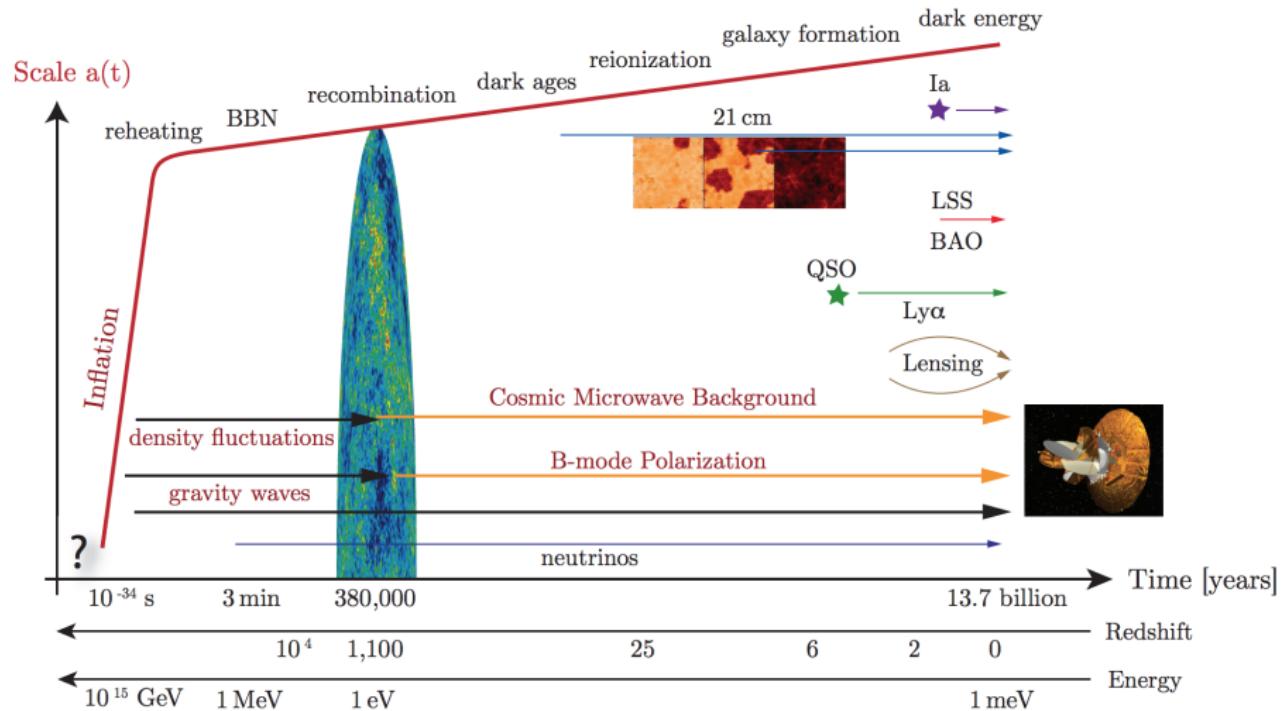

$$0.06 \text{ eV} \quad \lesssim \text{Planck} (\Lambda \text{CDM} + \sum m_\nu) + \text{BOSS} < 0.16 \text{ eV}$$

- Neutrino mass hierarchy  $\begin{cases} m_{\nu_1} < m_{\nu_2} \ll m_{\nu_3} \rightarrow \min(\sum m_\nu) \approx 0.06 \text{ eV} \\ m_{\nu_3} \ll m_{\nu_1} < m_{\nu_2} \rightarrow \min(\sum m_\nu) \approx 0.1 \text{ eV} \end{cases}$
- **Planck + DESI will yield**  $\sigma_{\sum m_\nu} = 0.017 \text{ eV}$
- Tritium  $\beta$ -decay (Troitzk):  $m_{\bar{\nu}_e} < 2.05 \text{ eV}$
- KATRIN forecast:  $m_{\bar{\nu}_e} \sim 0.2 \text{ eV}$  ( $\sum m_\nu \approx 0.6 \text{ eV}$ )

# Inflation in one plot

Baumann (2009)

# Testing inflation through primordial non-Gaussianity

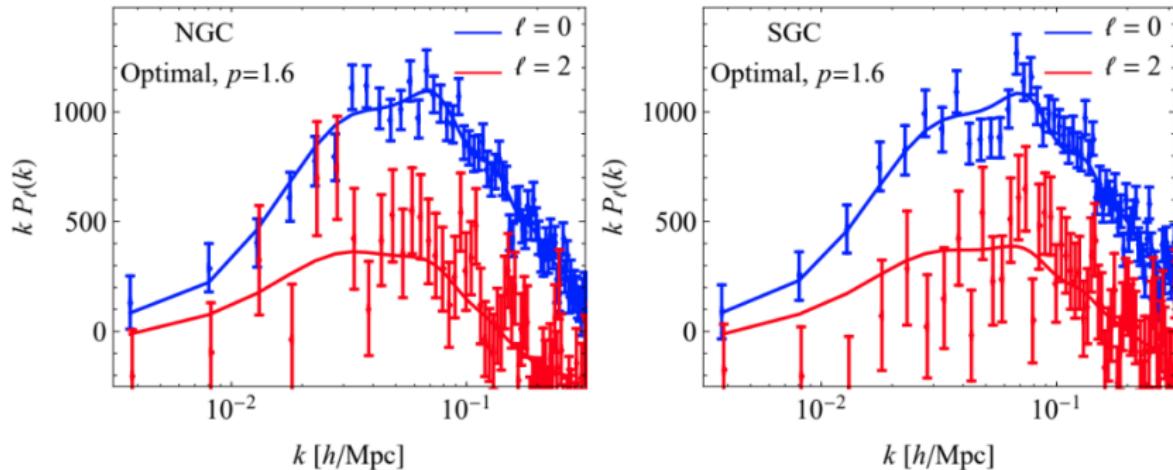

$$\phi_P = \phi + f_{NL}^{\text{loc}}(\phi^2 - \langle \phi^2 \rangle)$$

$$\delta_g(k) = \delta_m(k) \left( b_1 + f \mu^2 + \frac{b_\phi f_{NL}^{\text{loc}} \alpha}{k^2} \right)$$

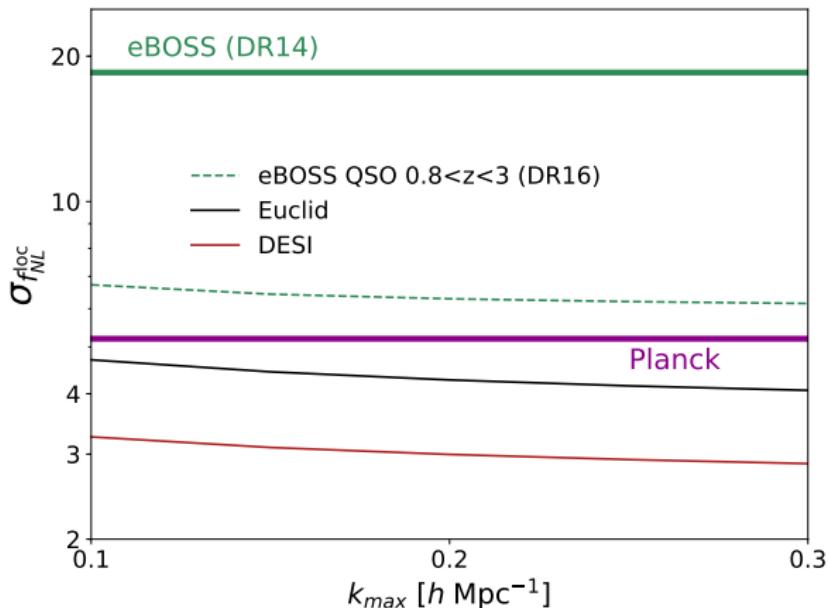

McDonald (2008)

# Primordial non-Gaussianity with LSS (preliminary)

- The CMB bispectrum yields  $f_{\text{NL}}^{\text{loc}} = 0.8 \pm 5.2$  (Planck col.)
- eBOSS DR14:  $\sim 150\,000$  Quasars at  $0.8 < z < 2.2$
- eBOSS provides the currently best LSS constraint  $f_{\text{NL}}^{\text{loc}} = -8^{+18}_{-19}$  using 1/3 of the final eBOSS sky coverage and excluding  $z > 2.2$

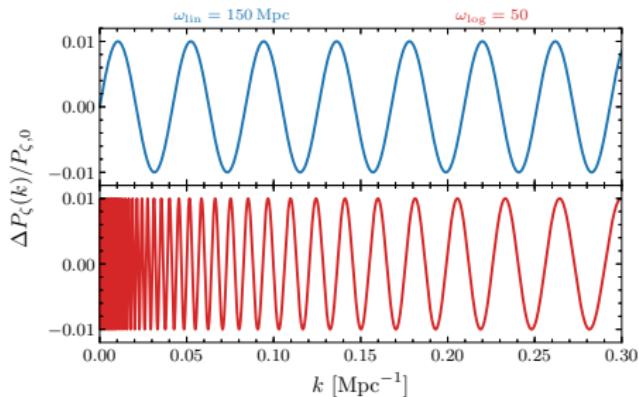

# Primordial non-Gaussianity with LSS

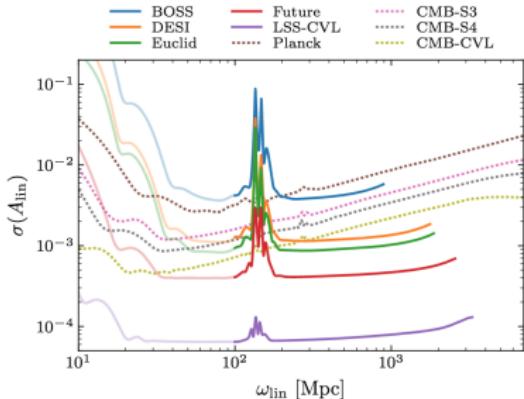

- **No bispectrum information included yet!**  $\rightarrow f_{NL}^{\text{equil}}, f_{NL}^{\text{ortho}}$
- **SPHEREx is now funded**  $\rightarrow \sigma_{f_{NL}^{\text{loc}}} < 1$  in 2025

# Testing inflation through primordial features

- Feature(s) in the inflationary potential can introduce features in the primordial power spectrum, which might still be detectable today.
- Sharp features can lead to linear oscillations, while periodic features lead to log-oscillations.
- Such features are predicted by many popular inflationary models like monodromy inflation, brane inflation, axion inflation etc.

# Testing inflation through primordial features

- Here we use a model-independent approach based on

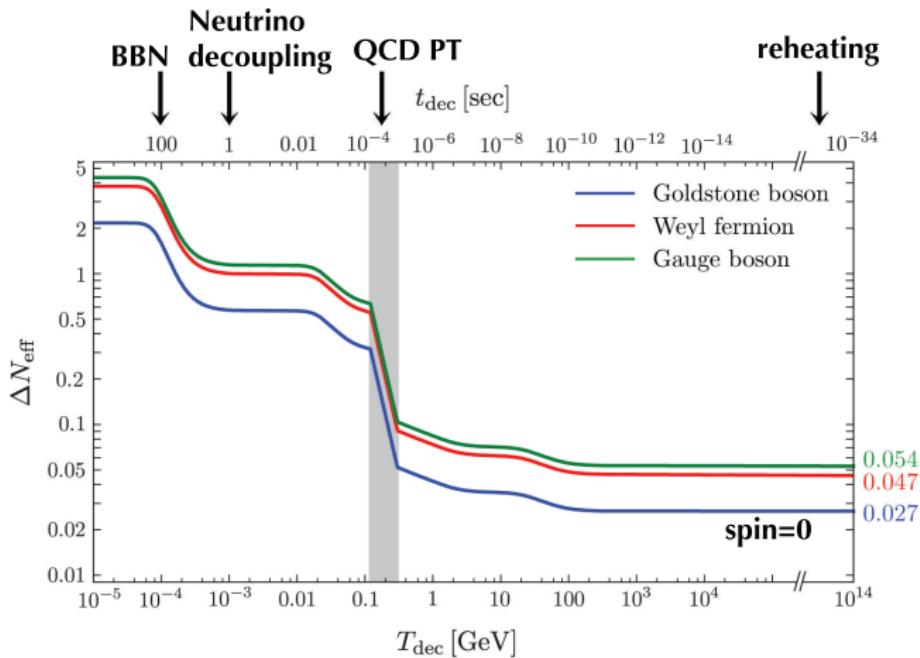

$$\frac{\Delta P_\zeta}{P_\zeta} = \begin{cases} A^{\cos} \cos \left[ \omega \log \log \left( \frac{k}{0.05} \right) \right] + A^{\sin} \sin \left[ \omega \log \log \left( \frac{k}{0.05} \right) \right], \\ A^{\cos} \cos [\omega_{\text{lin}} k] + A^{\sin} \sin [\omega_{\text{lin}} k] \end{cases}$$

- LSS is more powerful than the CMB on small frequencies, while the CMB can access much higher frequencies
- DESI is going to provide constraints which cannot be accessed even by a CVL CMB experiment

Beutler et al. in prep.

  - Baryon Acoustic Oscillations
  - Redshift-space distortions
- ② Testing inflation with primordial non-Gaussianity and primordial oscillations
- ③ Neutrinos in the phase of the BAO

# Motivation: Neutrinos in the phase of the BAO

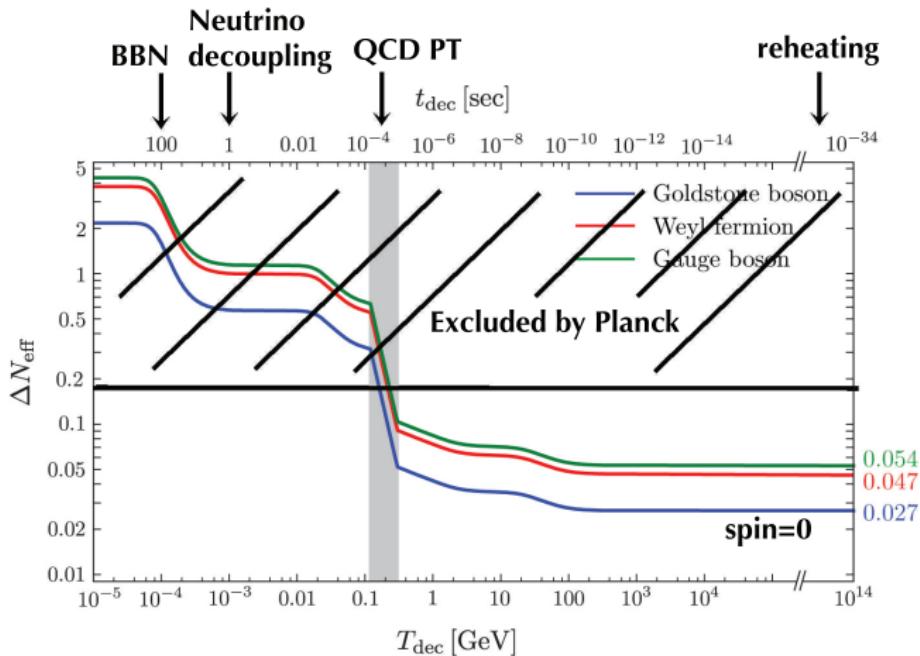

$$\rho_r = \left[ 1 + \frac{7}{8} \left( \frac{4}{11} \right)^{4/3} N_{\text{eff}} \right] \rho_\gamma$$

# Motivation: Neutrinos in the phase of the BAO

$$N_{\text{eff}} = 3.04 \pm 0.18 \quad (\text{Planck})$$

# Motivation: Neutrinos in the phase of the BAO

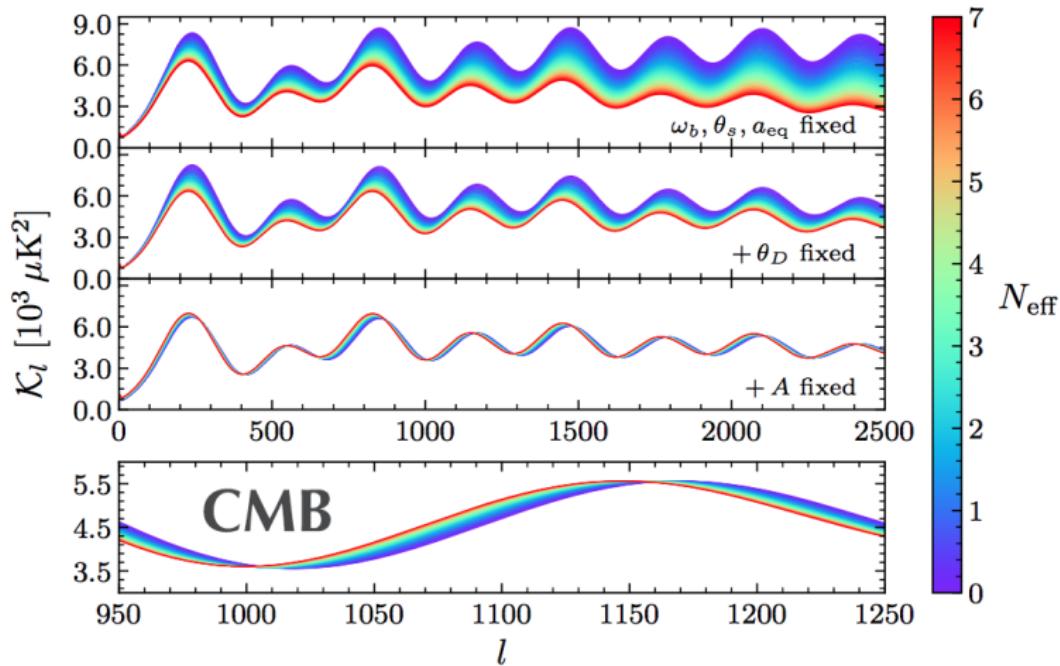

$$\sigma(N_{\text{eff}}) = 0.030 \quad (\text{CMB-S4})$$

$$\sigma(N_{\text{eff}}) = 0.027 \quad (\text{CMB-S4} + \text{Euclid})$$

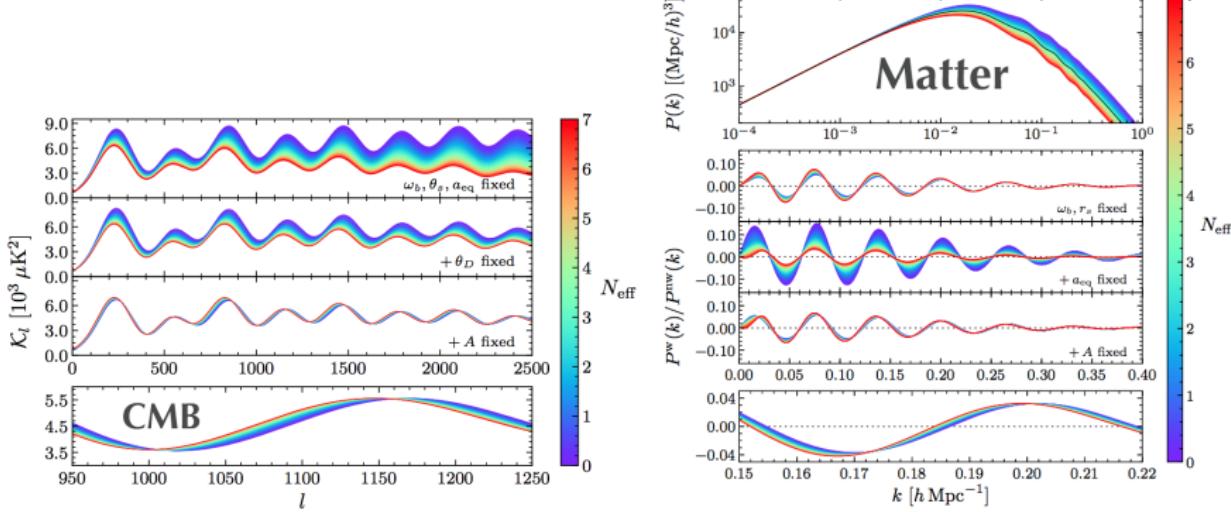

Baumann et al. (2017)

# Neutrinos in the CMB Spectrum

Current constraints are dominated by the damping of the power spectrum (degenerate with helium fraction).

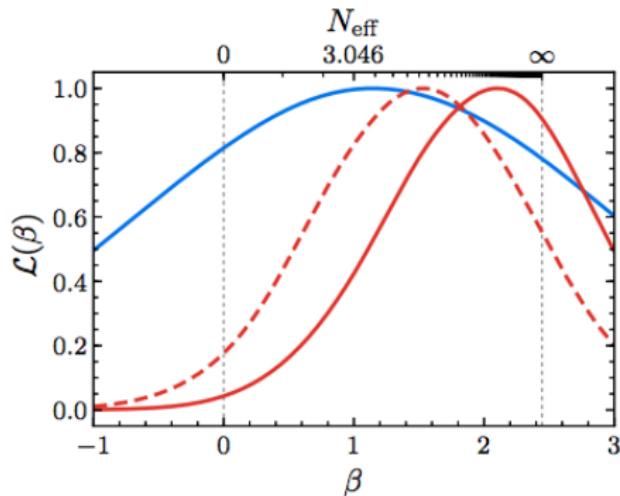

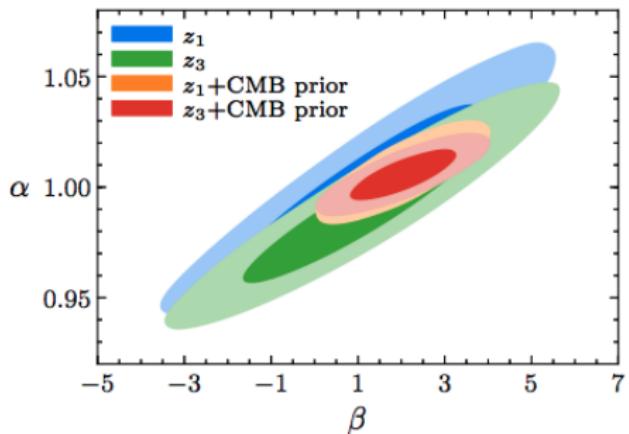

# Neutrinos in the BAO Spectrum

# Neutrinos in the BAO Spectrum

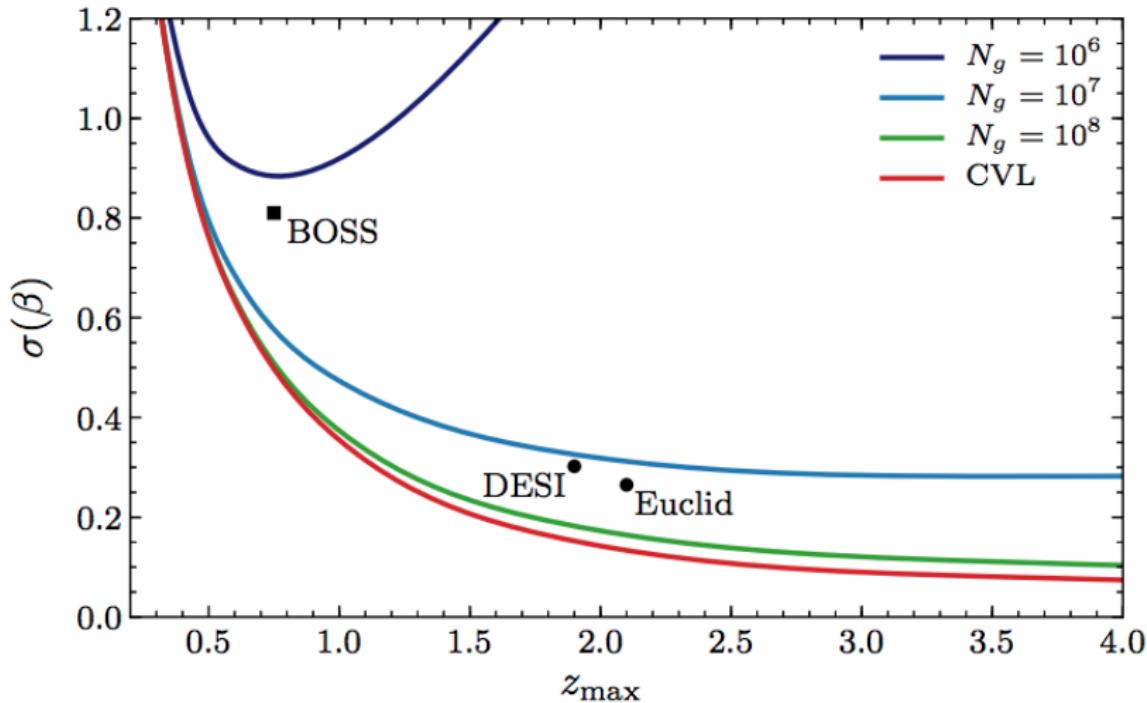

$$O(k) = O_{\text{lin}}(k/\alpha + (\beta - 1)f(k)/r_s^{\text{fid}}) e^{-k^2 \sigma_{\text{nl}}^2/2}$$

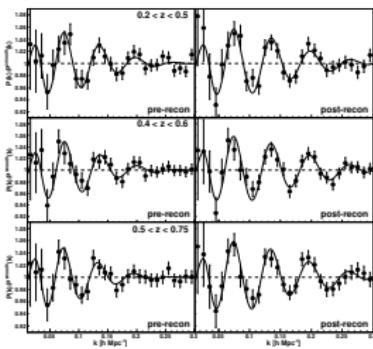

$$\beta(N_{\text{eff}}) = \frac{\epsilon}{\epsilon_{\text{fid}}} \quad \text{with} \quad \epsilon = \frac{N_{\text{eff}}}{8(11/4)^{4/3}/7 + N_{\text{eff}}}$$

→ This is a proof of principle for extracting information on light relics from galaxy clustering data.

# Neutrinos in the BAO Spectrum

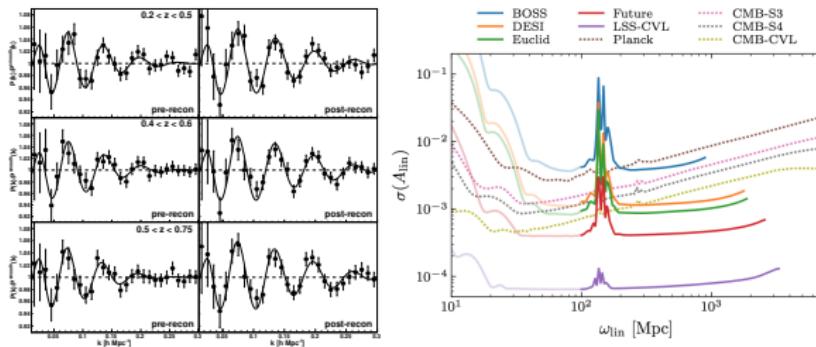

# Summary

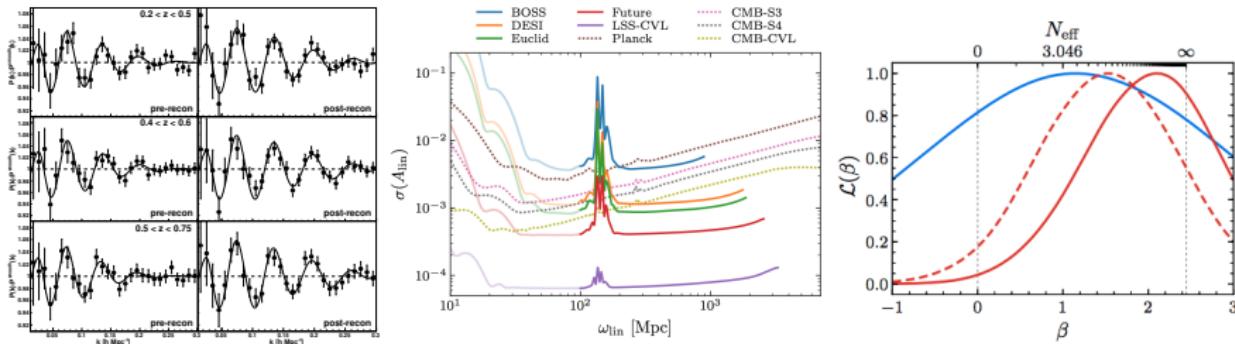

- 1 The next generation of galaxy surveys offers unprecedented cosmological constraints using BAO + RSD and **DESI will start this year.**

# Summary

- ① The next generation of galaxy surveys offers unprecedented cosmological constraints using BAO + RSD and **DESI will start this year.**
- ② LSS can constrain inflationary models competitive with the CMB using both **primordial non-Gaussianity** and **primordial features**.
- ③ Constraints on primordial features at high frequencies are **already dominated by LSS data.**

# Summary

- ① The next generation of galaxy surveys offers unprecedented cosmological constraints using BAO + RSD and **DESI will start this year**.
- ② LSS can constrain inflationary models competitive with the CMB using both **primordial non-Gaussianity** and **primordial features**.
- ③ Constraints on primordial features at high frequencies are **already dominated by LSS data**.
- ④ The **phase of the BAO** carries information on  $N_{\text{eff}}$  just as in the CMB. We have a **low significance detection in BOSS** and will be able to get  $\sim 3 - 5\sigma$  detections in DESI and Euclid.

# Research agenda

- ① What is the nature of inflation?
  - ↪ primordial features, primordial non-Gaussianity, primordial grav. waves
- ② What is the Neutrino mass scale and are there additional relativistic d.o.f. in the early Universe?
  - ↪ BAO, RSD, CMB lensing, Ly- $\alpha$  forest, weak lensing
- ③ What is the nature of dark matter and dark energy?
  - ↪ BAO... testing modified gravity with RSD
- Co-chair of the Euclid galaxy clustering working group (since 10/2015)
- Manager of the spectroscopic visibility mask and sample selection for Euclid (since 03/2016)
- Member of the DESI institutional board (Since 07/2018) and AI WG lead
- I led the BOSS DR11, Fourier-space RSD and neutrino mass analysis (Beutler et al. 2014), and the final BOSS, Fourier-space BAO and RSD analysis (Beutler et al. 2017a, 2017b)
- I led the BOSS-WiggleZ project → first BAO detection in cross-correlation (Beutler et al. 2015)

# Further linear corrections

At horizon scales further linear (GR) corrections start to matter:

$$\delta_g(k) = \delta_m(k) \left( b_1 + f\mu^2 \right) - \overbrace{\int_0^r dr' \frac{r-r'}{rr'} \Delta_\Omega(\Phi + \Psi)}^{\text{Lensing}}$$
$$+ \underbrace{\left( 1 - \frac{\dot{\mathcal{H}}}{\mathcal{H}^2} - \frac{2}{r\mathcal{H}} \right) v_{||} + \frac{1}{\mathcal{H}} \dot{v}_{||} + \frac{1}{\mathcal{H}} \partial_r \Psi}_{\text{Doppler}} + \underbrace{\Psi - 2\Phi + \frac{1}{\mathcal{H}} \dot{\Phi} + \frac{2}{r} \int_0^r dr' (\Phi + \Psi)}_{\text{grav. redshift}} \\ + \underbrace{\left( \frac{\dot{\mathcal{H}}}{\mathcal{H}^2} + \frac{2}{r\mathcal{H}} \right) \left[ \Psi + \int_0^r dr' (\dot{\Phi} + \dot{\Psi}) \right]}_{\text{Potential}}$$

# Fitting the BAO

- Start with linear  $P(k)$  and separate the broadband shape,  $P^{\text{sm}}(k)$ , and the BAO feature  $O^{\text{lin}}(k)$ . Include a damping of the BAO feature:

$$P^{\text{sm,lin}}(k) = P^{\text{sm}}(k) \left[ 1 + (O^{\text{lin}}(k/\alpha) - 1)e^{-k^2 \Sigma_{\text{nl}}^2 / 2} \right]$$

- Add broadband nuisance terms

$$A(k) = a_1 k + a_2 + \frac{a_3}{k} + \frac{a_4}{k^2} + \frac{a_5}{k^3}$$

$$P^{\text{fit}}(k) = B^2 P^{\text{sm,lin}}(k/\alpha) + A(k)$$

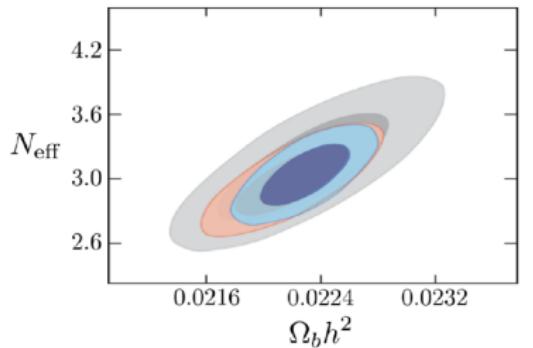

- Marginalize to get  $\mathcal{L}(\alpha)$ .

# Current constraints on $N_{\text{eff}}$

Relic neutrinos make up 41% of the radiation density

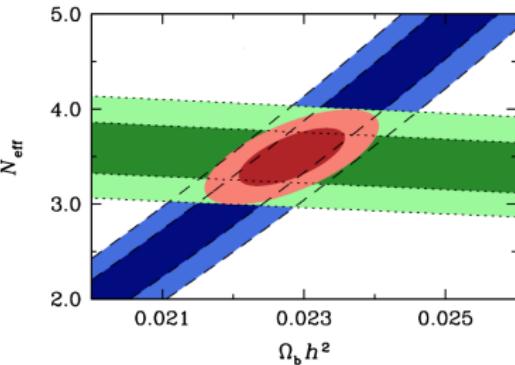

$$\rho_r = \left[ 1 + \frac{7}{8} \left( \frac{4}{11} \right)^{4/3} N_{\text{eff}} \right] \rho_\gamma$$

CMB

$$N_{\text{eff}}^{\text{CMB}} = 3.04 \pm 0.18$$

BBN

$$N_{\text{eff}}^{\text{BBN}} = 3.28 \pm 0.28$$

Planck (2015), Cooke et al. (2015)

# New decomposition formalism for the bispectrum

The estimator is based on the spherical harmonics expansion

$$\begin{aligned}\widehat{B}_{\ell_1 \ell_2 L}(k_1, k_2) &= H_{\ell_1 \ell_2 L} \sum_{m_1 m_2 M} \left( \begin{smallmatrix} \ell_1 & \ell_2 & L \\ m_1 & m_2 & M \end{smallmatrix} \right) \\ &\times \frac{N_{\ell_1 \ell_2 L}}{I} \int \frac{d^2 \hat{k}_1}{4\pi} y_{\ell_1}^{m_1 *}(\hat{k}_1) \int \frac{d^2 \hat{k}_2}{4\pi} y_{\ell_2}^{m_2 *}(\hat{k}_2) \\ &\times \int \frac{d^3 k_3}{(2\pi)^3} (2\pi)^3 \delta_D(\vec{k}_1 + \vec{k}_2 + \vec{k}_3) \\ &\times \delta n(\vec{k}_1) \delta n(\vec{k}_2) \delta n_L^M(\vec{k}_3)\end{aligned}$$

where  $y_L^{M*}$ -weighted density fluctuation

$$\begin{aligned}\delta n_L^M(\vec{x}) &\equiv y_L^{M*}(\hat{x}) \delta n(\vec{x}) \\ \delta n_L^M(\vec{k}) &= \int d^3 x e^{-i\vec{k}\cdot\vec{x}} \delta n_L^M(\vec{x})\end{aligned}$$

$$\text{and } y_\ell^m = \sqrt{4\pi/(2\ell+1)} Y_\ell^m.$$

## Why using this formalism

- This decomposition compresses the data into 2D quantities  $B_{\ell_1 \ell_2 L}(k_1, k_2)$  rather than 3D quantities like other decompositions  $B_\ell^m(k_1, k_2, k_3)$ . This reduces the size of the connected covariance matrix.
- This decomposition allows for a self consistent inclusion of the survey window function.
- The RSD information is clearly separated into the  $L$  multipoles.
- The complexity of our estimator is  $O((2\ell_1 + 1)N_b^2 N \log N)$ .
- Only some multipoles are non-zero: (1)  $\ell_1 > \ell_2$  (2)  $L = \text{even}$  (3)  $|\ell_1 - \ell_2| \leq L \leq |\ell_1 + \ell_2|$  and (4)  $\ell_1 + \ell_2 + L = \text{even}$ .
